Inference and Representation, Fall 2017

Problem Set 2: Undirected graphical models & Modeling exercise

Due: Monday, September 25, 2017 at 3pm (as a PDF file uploaded to NYU Classes)

Important: *See problem set policy on the course web site.*

---

1. Exercise 4.1 from Koller & Friedman (requirement of positivity in Hammersley-Clifford theorem; see also page 116).

2. Recall that an Ising model is given by the distribution

$$p(x_1, \cdots, x_n) = \frac{1}{Z} \exp\Big(\sum_{(i,j) \in E} w_{i,j} x_i x_j - \sum_{i \in V} u_i x_i \Big), \tag{1}$$

   where the random variables $X_i \in \{-1, +1\}$. Related to the Ising model is the *Boltzmann machine*, which is parameterized the same way (i.e., using Eq. 1), but which has variables $X_i \in \{0, 1\}$. Here we get a non-zero contribution to the energy (i.e. the quantity in the parentheses in Eq. 1) from an edge (i, j) only when $X_i = X_j = 1$.

   Show that a Boltzmann machine distribution can be rewritten as an Ising model. More specifically, given parameters $\vec{w}, \vec{u}$ corresponding to a Boltzmann machine, specify new parameters $\vec{w}', \vec{u}'$ for an Ising model and prove that they give the same distribution $p(\mathbf{X})$ (assuming the state space $\{0, 1\}$ is mapped to $\{-1, +1\}$).

3. Give a procedure to convert any Markov network on discrete variables into a pairwise Markov random field. In particular, given a distribution $p(\mathbf{X})$, specify a new distribution $p'(\mathbf{X}, \mathbf{Y})$ which is a pairwise MRF, such that $p(\mathbf{x}) = \sum_{\mathbf{y}} p'(\mathbf{x}, \mathbf{y})$, where $\mathbf{Y}$ are any new variables added.

   Clarification: Assume that the input is specified as full tables specifying the value of the potential for every assignment to the variables for each potential. The new pairwise MRF must have a description which is polynomial in the size of the original MRF.

   Hint: First consider a simple case, such as a MRF on 3 binary variables with a single potential function for the 3 variables, i.e. $p(\mathbf{X}) \propto \psi_{123}(X_1, X_2, X_3)$. Introduce a new variable Y with $2^3 = 8$ states and let $p'(\mathbf{X}, Y) \propto \psi_Y(Y)\psi_{1Y}(X_1, Y)\psi_{2Y}(X_2, Y)\psi_{3Y}(X_3, Y)$. Figure out how to set the new potential functions $\psi_Y(Y), \psi_{1Y}(X_1, Y), \psi_{2Y}(X_2, Y)$ and $\psi_{3Y}(X_3, Y)$ so as to have $p(\mathbf{x}) = \sum_y p'(\mathbf{x}, y)$ for all assignments $\mathbf{x}$.

4. **Exponential families**. Probability distributions in the exponential family have the form:

$$p(\mathbf{x}; \eta) = h(\mathbf{x}) \exp\{\eta \cdot \mathbf{f}(\mathbf{x}) - \ln Z(\eta)\}$$

   for some scalar function $h(\mathbf{x})$, vector of functions $\mathbf{f}(\mathbf{x}) = (f_1(\mathbf{x}), \ldots, f_d(\mathbf{x}))$, canonical parameter vector $\eta \in \mathbb{R}^d$ (often referred to as the *natural parameters*), and $Z(\eta)$ a constant (depending on η) chosen so that the distribution normalizes.

   (a) Determine which of the following distributions are in the exponential family, exhibiting the $\mathbf{f}(\mathbf{x})$, $Z(\eta)$, and $h(\mathbf{x})$ functions for those that are.

i. $N(\mu, I)$—multivariate Gaussian with mean vector μ and identity covariance matrix.
ii. $\mathrm{Dir}(\alpha)$—Dirichlet with parameter vector $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_K)$ (see Sec. 2.5.4).
iii. log-Normal distribution—the distribution of $Y = \exp(X)$, where $X \sim N(0, \sigma^2)$.
iv. Boltzmann distribution—an undirected graphical model $G = (V, E)$ involving a binary random vector $\mathbf{X}$ taking values in $\{0,1\}^n$ with distribution $p(\mathbf{x}) \propto \exp\big\{\sum_i u_i x_i + \sum_{(i,j)\in E} w_{i,j} x_i x_j\big\}$.

(b) *Conditional models.* One can also talk about conditional distributions being in the exponential family, being of the form:

$$p(\mathbf{y} \mid \mathbf{x}; \eta) = h(\mathbf{x}, \mathbf{y}) \exp\{\eta \cdot \mathbf{f}(\mathbf{x}, \mathbf{y}) - \ln Z(\eta, \mathbf{x})\}.$$

The partition function Z now depends on $\mathbf{x}$, the variables that are conditioned on. Let Y be a binary variable whose conditional distribution is specified by the logistic function,

$$p(Y = 1 \mid \mathbf{x}; \alpha) = \frac{1}{1 + e^{-\alpha_0 - \sum_{i=1}^{n} \alpha_i x_i}}$$

Show that this conditional distribution is in the exponential family.

5. **Tree factorization.** Let T denote the edges of a tree-structured pairwise Markov random field with vertices V. For the special case of trees, prove that *any* distribution $p_T(\mathbf{x})$ corresponding to a Markov random field over T admits a factorization of the form:

$$p_T(\mathbf{x}) = \prod_{(i,j)\in T} \frac{p_T(x_i, x_j)}{p_T(x_i) p_T(x_j)} \prod_{j \in V} p_T(x_j), \tag{2}$$

where $p_T(x_i, x_j)$ and $p_T(x_i)$ denote pairwise and singleton marginals of the distribution p_T, respectively.

Hint: consider the Bayesian network where you choose an arbitrary node to be a root and direct all edges away from the root. Show that this is equivalent to the MRF. Then, looking at the BN's factorization, reshape it into the required form.
